(54) **DVD audio disk reproducing device and method thereof**

(57) A DVD audio disk on a lead-in area of which an audio title information management table is stored, and on a data area of which an audio pack of linear PCM mode is stored, wherein first, second and third quantization bits, first, second and third sampling frequencies, and information relative to the number of audio channels

are all recorded on the title information management table, the audio pack being provided with audio packets made up with the quantization bits, the sampling frequencies and the information relative to the number of channels all recorded on the title management table, the packets further containing audio data.

## Description

The present invention relates to an audio disk, a device and method for reproducing audio data recorded thereon and more particularly, to a disk on which high-quality audio data is recorded and a device and method for reproducing audio data recorded on the disk.

Generally speaking, audio data recorded on a compact disk (CD) is sampled at 44.1KHz, and each of the samples is audio data quantized by 16 bits. Such a CD is advantageous in usage and storage, as compared with conventional long playing records (LPs), while it has often been said that the CD has an inferior sound quality. For instance, when audio data sampled at 44.1KHz and quantized by 16 bits is reproduced, it is difficult to reproduce the original sound and it may be deteriorated compared with the disk used in the generation prior to CD. Actually, the humanly audible frequency range may be over 20KHz, with a dynamic range of 120dB. With the CD, it is impossible to record or reproduce audio data related to multi-channel music which has increasingly concentrated interest, because it can only record audio signals with a maximum of two channels.

Coping with those problems, there have been suggested methods of improving the sound quality reproduced, by increasing the sampling frequency of the audio data and the number of recording channels.

Currently, a disk reproducing device has been designed to reproduce a variety of disks. One such disk type is a digital versatile disk (DVD). With the DVD, video and audio data is recorded at a high density, and the video data is recorded in the MPEG format. The audio data is recorded in the linear pulse code modulation (PCM), Dolby AC-3, or MPEG format. The device for reproducing the DVD video disk has a configuration of reproducing video/audio data so as to retrieve the video/audio data recorded on the DVD-video disk.

On the lead-in area of the DVD video disk, a video title set information management table (VTSI\_MAT) is recorded, and on the data area sequential thereto, the audio/video data are recorded. The audio data recorded on the data area of the DVD video disk has the structure of audio pack. Here, first, the VTSI\_MAT and then the structure of audio pack will be inspected.

As mentioned above, the DVD video disk has the VTSI\_MAT which contains information for reproducing video data and audio data. This is shown in the following tables 1a, 1b, 2a and 2b.

[ Table 1a ]

RBP		Contents	Number of Bytes

In the VTSI\_MAT of the tables 1a, 1b, 2a and 2b, VTSM\_AST\_ATR of RBP 260-267 indicates the audio stream attribute of VTSM\_VOBS, which is shown in Figure 1. The respective fields' values become the internal information of the audio stream of VTSM\_VOBS. Referring to Figure 1, the information of the audio coding mode recorded on b63-b61 is stored as in the following table 3.

[ Table 3 ]

b63-b61	Audio Coding Mode
000b	Dolby AC-3
010b	MPEG-1 or MPEG-2 where no extension bit stream exists
011b	MPEG-1 where extension bit stream exists
100b	Linear PCM Audio
others	Reserved

In b55-b54, quantization/DRC information is stored as follows. If the audio coding mode is "000b", 11b is recorded. If the audio coding mode is 010b or 011b, the quantization information is defined as follows.

## EP 0 855 715 A2

00b: the dynamic range control data is not present in the MPEG audio stream.

01b: the dynamic range control data is present in the MPEG audio stream.

10b: reserved

11b: reserved

If the audio coding mode is 100b, the quantization information is stored as shown in table 4.

[ Table 4 ]

b55-b54	Quantization DRC
00b	16bits
01b	20bits
10b	24bits
11b	Reserved

b53-b52 indicative of sampling frequency  $f_s$  in Figure 1 is shown in table 5.

[ Table 5 ]

b53-b52	$f_s$
00b	48KHz
01b	96KHz
10b	Reserved
11b	Reserved

b50-b28 indicative of the number of audio channels in Figure 1 is shown in table 6.

[ Table 6 ]

b50-b28	Number of Audio Channels
000b	1ch (mono)
001b	2ch (stereo)
010b	3ch (multichannel)
011b	4ch (multichannel)
100b	5ch (multichannel)
101b	6ch (multichannel)
110b	7ch (multichannel)
111b	8ch (multichannel)
others	Reserved

In the VTSI\_MAT of the tables 1a, 1b, 2a and 2b, VTS\_AST\_ATRT of RBP 516-579 indicates the audio stream attribute of VTS, which is shown in Figure 2. The respective fields' values become the internal information of the audio stream of VTSM\_VOBS. Referring to Figure 2, the information of the audio coding mode recorded on b63-b61 is stored as in the following table 7.

[ Table 7 ]

b63-b61	Audio Coding Mode
000b	Dolby AC-3
010b	MPEG-1 or MPEG-2 where no extension bit stream exists
011b	MPEG-2 where extension bit stream exists

[ Table 7 ] (continued)

b63-b61	Audio Coding Mode
100b	Linear PCM Audio
110b	DTS (option)
111b	SDDS (option)
others	Reserved

The multi-channel extension of b60 is an area which stores information indicative of whether the multi-channel extension is executed or not. If 0b is recorded, this means that the multi-channel extension is not selected. If 1b is recorded, this means that the multi-channel extension is performed according to the information of VTS\_MU\_AST\_ATRT recorded on RBP 792-983.

The audio type of b59-b58 is shown as in the following table 8.

[ Table 8 ]

b59-b58	Audio Type
00b	Not Specified
01b	Language Included
others	Reserved

The audio application mode of b57-56 is shown in the following table 9.

[ Table 9 ]

b57-b56	Audio Application Mode
00b	Not Specified
01b	Karaoke Mode
10b	Surround Mode
11b	Reserved

The quantization/DRC, sampling frequency  $f_s$ , and the number of audio channels are shown in tables 4, 5, and 6, respectively.

In the VTSI\_MAT of tables 1a, 1b, 2a and 2b the VTS\_MU\_AST\_ATRT of RBP 792 - 983 indicates the multi-channel audio stream attribute table of VTS, which is shown in Figures 3a and 3b. This VTS\_MU\_AST\_ATRT has two types, that is, VTS\_MU\_AST\_ATRT (1) shown in Figure 3a and VTS\_MU\_AST\_ATRT (2) shown in Figure 3b. If 0b is written in b60 of VTS\_MU\_AST\_ATRT of Figure 2, 0b is stored all the bits which store the audio stream.

The DVD reproducing device analyzes the information written in the VTSI management table recorded on the DVD video disk, and reproduces the video/audio data written on the disk. Here, the audio data and video data written on the DVD video disk are made in units of packs. Figure 4 shows the structure of a pack having no padding packet in the DVD. Referring to Figure 4, one pack has a size of 2048 bytes, with 14 bytes of pack header and 2034 bytes of packet for video, audio, sub-picture, DSI or PCI. The packet header of 14 bytes contains 4 bytes of pack start code, 6 bytes of SCR, 3 bytes of program\_mux\_rate, and one byte of stuffing\_length.

Figures 5a-5e show the structure of the audio pack used in the DVD video. Specifically referring to Figure 5a which depicts the structure of the linear PCM audio pack, it is made up with 14 bytes of pack header and 2034 bytes of linear audio packet. Here, the audio packet has one byte of packet header, one byte of sub\_stream\_id, 3 bytes of audio frame information, 3 bytes of audio data information, one byte to 2013 bytes of linear PCM audio data.

Figure 5b shows the structure of the Dolby AC-3 audio pack. Referring to Figure 5b, the pack has 14 bytes of pack header and 2034 bytes of Dolby AC-3 audio packet. The audio packet has one byte of packet header, one byte of sub\_stream\_id, 3 bytes of audio frame information, one byte to 2016 bytes of AC-3 audio data.

Figure 5c shows the structure of MPEG-1 audio or MPEG-2 audio pack having no extension bitstream. Figures 5d and 5e show the structure of MPEG-2 audio pack having an extension stream. The audio packs shown in Figures 5a-5e have the same structure of tables 10a and 10b, respectively, and private data areas corresponding to the respective formats separately.

[ Table 11 ] (continued)

Field	Number of Bits	Number of Bytes	Value	Comment
Note 8: "audio_sampling_frequency" is the sampling frequency used in the sampling of the audio sample.				
			00b: 48KHz	
			01b: 96KHz	
			others: reserved	
Note 9: "number_of_channels" indicates the number of audio channels.				
			000b: 1ch (mono)	
			001b: 2ch (stereo)	
			010b: 3ch (multi-channel)	
			011b: 4ch (multi-channel)	
			100b: 5ch (multi-channel)	
			101b: 6ch (multi-channel)	
			110b: 7ch (multi-channel)	
			111b: 8ch (multi-channel)	
Note 10: "dynamic range control" indicates the dynamic range control word for compressing the dynamic range from the first access unit.				

The stream id in the audio packets shown in Figures 5a-5e is determined as follows. First of all, the stream id of the linear PCM audio packet becomes 1011 1101b (private\_stream\_1), its sub\_stream\_id being 1010 0\*\*\*b. Second, the stream id of the AC-3 audio packet becomes 1011 1101b (private\_stream\_1), its sub\_stream\_id being 1000 0\*\*\*b. Third, the stream id of the MPEG audio packet becomes 1100 0\*\*\*b or 1101 0\*\*\*b, having no sub\_stream\_id. In the stream id or sub\_stream\_id, \*\*\*\*\* indicates the decoding audio stream number having a value between 0 and 7. The decoding audio stream number is not allocated with the same number, regardless of the audio compression mode.

Figure 6 is a diagram for explaining the structure of the audio pack and audio stream. The audio data used in the DVD can be linear PCM data, Dolby AC-3 data, or MPEG audio data. Such audio stream is divided into a plurality of audio packs, as shown in Figure 3. These audio packs are controlled in units of 2048 bytes. Here, the coding format of the linear PCM audio data is as shown in table 12.

[ Table 12 ]

Sampling frequency (fs)	48KHz	96KHz
Sampling Phase	Shall be simultaneous for all channels in a stream	
Quantization	over 16 bits, 2's complementary code	
Emphasis	applied (zero point 50μs, pole:15μs)	not applied

In Table 12, the linear PCM audio stream data is made up with adjacent GOFs, each GOF having 20 audio frames except the final GOF. The final GOF is made to be equal to or smaller than 20 audio frames.

Figure 7 shows the structure of the audio frame. Referring to Figure 7, one audio frame has sample data in accordance with 1/600 seconds. If sampling frequency fs = 48 KHz, one audio frame contains 80 audio sample data. If sampling frequency fs = 96 KHz, one audio frame contains 160 audio sample data. One GOF coincides with 1/30 seconds.

Figures 8a - 8c show sample data alignments for linear PCM. The sample data consists of pieces of the respective channel data sampled at the same time. The size of the sample data varies with the audio stream attribute, each sample data being arranged continuously. Figures 8a, 8b and 8c show two formats of sample data at the respective modes. Here, Figure 8a shows the alignment of sample data of 16-bit mode. Figure 8b shows the alignment of sample data of 20-bit mode. Figure 8c shows the alignment of sample data of 24-bit mode.

The structure of the packet data of the linear PCM audio is shown in table 13.

[ Table 13 ]

Stream Mode			Data in a packet			
Number of Channels	fs(KHz)	Quantization (bits)	Maximum number of samples in a packet	Date size (byte)	Packet stuffing of first/other PES packet (byte)	Padding packet for first/ other PES packet (byte)
1(mono)	48/96	16	1004	2008	2/5	0/0
	48/96	20	804	2010	0/3	0/0
	48/96	24	670	2010	0/3	0/0

	48/96	24	334	2004	6/0	0/9
3	48/96	16	334	2004	6/0	0/9
	48/96	20	268	2010	0/3	0/0
	48	24	222	1988	0/0	12/15
4	48/96	16	250	2000	0/0	10/13
	48	20	200	2000	0/0	10/13
	48	24	166	1992	0/0	18/21
5	48	16	200	2000	0/0	10/13
	48	20	160	2000	0/0	10/ 13
	48	24	134	2010	0/3	0/0
6	48	16	166	1992	0/0	18/21
	48	20	134	2010	0/3	0/0
7	48	16	142	1988	0/0	22/25
8	48	16	124	1984	0/0	26/29

If the number of samples is smaller than the values of table 13, the length of padding packet increases in order to control the pack size. The samples are assigned to the packet boundary. In other words, the sample data of all the audio packet for the linear PCM audio always starts with the first byte of  $S_{2n}$ , as shown in table 13.

Explaining the channel assignment of the linear PCM, ACHO and ACHI channels correspond to L channel and R channel in the stereo mode, respectively. The multi-channel mode is coded to be compatible with the stereo mode.

As the audio option of the DVD, there is a digital theater system (DTS). The audio pack of the DTS has the pack header and audio packets, as shown in Figure 9. The audio pack is aligned to the boundary between the LBs within the audio frame units. Referring to Figure 9, one audio pack is composed of 14 bytes of pack header and 2021 bytes of DTS audio packet. The DTS audio packet has one byte of packet header, one byte of sub\_stream\_id, 3 bytes of audio frame information, and one byte to 2016 bytes of DTS audio data. The stream id of the DTS audio packet is 1011 1101b (private\_1), its sub\_stream\_id being 1000 1\*\*\*b. Here, \*\*\* of the sub\_stream\_id indicates the decoding audio stream number having a value of 0 to 7. The decoding audio stream numbers are not assigned with the same number, regardless of the audio compression mode.

The structure of the DTS audio packet is shown in table 10, the private data area being in table 14.

[ Table 14 ]

Field	Number of Bits	Number of Bytes	Value	Comment
sub_stream_id	8	1	1000 1***b	Note 1
number_of_frame_headers	8	1	provider defined	Note 2

[ Table 14 ] (continued)

Field	Number of Bits	Number of Bytes	Value	Comment
First-access_unit_pointer	16	2	provider defined	Note 3
DTS audio data area				
In table 14, Note 1 - Note 3 are shown in the following.				
Note 1: "****" indicates the decoding audio stream number.				
Note 2: "number_of_frame_headers" indicates the audio frame number where the first byte exists in the DTS audio packet.				
Note 3: The access unit is audio frame. The first access unit is the audio frame having the first byte of the audio frame, defined as the PTS of the audio pack. "first_access_unit_pointer" indicates the first byte address of the first access unit with RBN from the final byte of the information area. If the first byte of the first access unit does not exist, 0000 0000h is recorded.				

The DTS is provided with the DTS standards for the multi-channel sound of high quality. The DTS standards are shown in table 15.

[ Table 15 ]

Bit Rate	mono(1ch) 64k to 384k bps stereo(2ch) 96k to 769k bps 5.1 channel 256k to 1536k bps
Sampling Frequency	48KHz Only
Audio Coding Mode	1/0, 2/0, 3/0, 2/1, 2/2, 3/2, *1
Protection	CRC disabled
Multilingual Channels	0
In table 15, *1 is useful to the low frequency effects channels in the respective audio modes. The DTS audio having such packet structure can be defined as the multi-channel sound of high quality.	

The number of channel available of linear PCM in the DVD video is shown in Figure 10. In Figure 10, the maximum bit rate is 6.75Mbps, and the channel is determined as in table 16.

[ Table 16 ]

Sampling Frequency	Number of Quantization Bits	Number of Channels
48KHz	16 bit	8 channel
	20 bit	6 channel
	24 bit	5 channel
96KHz	16 bit	4 channel
	20 bit	3 channel
	24 bit	2 channel

The audio data recorded on the DVD-video disk has a far better sound quality than that on the CD audio disk. The audio data recorded on the DVD disk has a sampling frequency, and the number of quantization bits and the number of channels greater than those on the CD audio disk. Therefore, the DVD reproducing device can reproduce high sound quality of audio data with multi-channel.

The DVD video disk enables maximum 10.08Mbps of data transmission. With reference to this, it is noted that data sampled at 192KHz can be reproduced with two channels. These values approximate the maximum sampling frequency designated as the requirements necessary in the next-generation audio in the advanced digital audio conference held in April, 1996 in Japan. If the pure audio data is recorded on the DVD disk, and the DVD reproducing device plays back the DVD audio disk, much improved sound quality of audio signal is obtained.

An aim of embodiments of the present invention is to provide a DVD audio disk which is capable of recording sampled digital audio signals in a linear PCM mode up to the number of channels limited by the transmission velocity

of the data, by using the sampling frequency of maximum 192KHz and the number of 24 quantization bits.

Another aim of embodiments of the present invention is to provide a DVD audio disk which is capable of encoding the sampled digital audio signal in a set mode, and recording it up to the number of channels limited by the transmission velocity of the data and the coding mode by using the sampling frequency of maximum 192KHz and maximum 24 bits of the number of quantization bits.

Still another aim of embodiments of the present invention is to provide a device and method for reproducing a DVD audio disk recorded in the linear PCM mode.

Yet another aim of embodiments of the present invention is to provide a device and method for reproducing a DVD audio disk which stores the compressed audio data.

A further aim of embodiments of the present invention is to provide a device and method for discriminating a DVD video or audio disk, and reproducing it according to the discrimination result.

According to a first aspect there is provided a DVD audio disk to store audio data, comprising: information areas each storing an audio title information management table; and respective data areas each storing audio packs of a linear pulse code modulated (PCM) mode; wherein the audio title information management table includes a first, second or third number of quantization bits corresponding to the audio data, a first, second or third sampling frequency corresponding to the audio data, and information relative to a number of audio channels of the audio data, and each audio pack including audio packets having the first, second or third number of quantization bits, the first, second or third sampling frequency and the information relative to the number of channels which are recorded in the audio title information management table, and the audio packets further containing corresponding portions of the audio data.

Preferably, the first, second and third quantization number of bits are 16, 20, and 24 bits, respectively, the first, second and third sampling frequencies are 48, 96, and 192KHz, respectively, a maximum number of the audio channels being 13, and the number of channels being determined by the following equation:

$$N = \frac{Mbr}{Fs * Qb}$$

Wherein, Fs is the sampling frequency (Hz) of the audio data, Qb is the number of quantization bits of the audio data, Mbr is a maximum data transmission rate (Mbps) of the DVD audio disk, and N is a maximum number of recordable channels as determined by the maximum data transmission rate, sampling frequency, and the number of quantization bits of the DVD disk.

According to a second aspect there is provided a DVD audio disk to store audio data, comprising: information areas each storing a title information management table; and respective data areas each storing a pseudo-lossless psychoacoustic coding mode; wherein the title information management table includes a first, second or third number of quantization bits corresponding to the audio data, a first, second or third sampling frequency corresponding to the audio data, and information relative to a number of audio channels of the audio data, and each audio pack including audio packets having the first, second or third number of quantization bits, the first, second or third sampling frequency, and the information relative to the number of channels which are recorded in the title information management table, and the packets further containing corresponding portions of the audio data.

Preferably, the pseudo-lossless psychoacoustic coding mode uses a Digital Theatre System (DTS) compressive coding mode, the first, second and third numbers of quantization bits of the audio data prior to compression are 16, 20, and 24 bits, respectively, the first, second and third sampling frequencies are 48, 96, and 192 KHz, respectively, a maximum number of the audio channels being 16 and, the number of channels being determined by the following equation:

$$N = \frac{Mbr * Ccr}{Fs * Qb}$$

Wherein, Fs is the sampling frequency (Hz), of the audio data, Qb is the number of quantization bits of the audio data, Mbr is a maximum data transmission rate (Mbps) of the DVD audio disk, Ccr is a compression ratio in accordance with the DTS compressive coding mode, and N is a maximum number of recordable channels as determined by the data transmission rate, the sampling frequency, the number of quantization bits, and the compression ratio of the DVD audio disk.

According to a third aspect there is provided a DVD audio disk to store audio data, comprising: information areas each storing a title information management table; and respective data areas each storing sequential audio packs; wherein the DVD audio disk conforms to the MPEG2 system layer standards; wherein the title information management table has an audio stream attribute area which includes an audio coding mode, a number of quantization bits, and a sampling frequency related to the audio packs, and information related to the number of audio channels, each of the audio packs includes a pack header and audio packets; each of the audio packets includes a packet header, sub-

stream ID, audio frame information, audio data information, and a portion of the audio data; and the number of channels of audio data received is determined by the following equation:

$$N = \frac{Mbr * Ccr}{Fs * Qb}$$

and wherein  $F_s$  is the sampling frequency (Hz), having a value of one of 48KHz, 96KHz and 192KHz  $Q_b$  is the number of quantization bits having a value of one of 16 bits, 20 bits, and 24 bits,  $Mbr$  is a maximum data transmission rate (10.08Mbps) of the DVD audio disk,  $Ccr$  is a compression ratio in accordance with a compressive coding mode, and  $N$  is a maximum number of recordable channels as determined by the data transmission rate, the sampling frequency, the number of quantization bits, and the compression ratio of the DVD audio disk.

According to another aspect of the invention there is provided a DVD audio disk reproducing device comprising: a data receiver to receive audio data reproduced from a disk; a controller to analyze the audio data reproduced from the disk to thereby generate an audio control signal containing an audio coding mode, a sampling frequency, a number of channels and quantization information; an audio decoder having a plurality of decoders, one of the plurality of decoders to decode the audio data received after being selected according to the audio coding mode of the audio data, including multi-channel mixing, sampling frequency converting and requantizing the decoded audio data, according to the audio control signal; and an audio output to convert the audio data into an analog audio signal.

Preferably, the audio decoder comprises: a stream selector to select one of a plurality of audio streams, which form the audio data according to the audio coding mode; a linear PCM decoder to decode the selected audio stream if the selected audio stream is a linear PCM audio stream output from the stream selector, the linear PCM decoder sampling frequency converting, multi-channel down mixing and requantizing the decoded audio data decoded according to the audio control signal; and a data decoder to decode the selected audio stream if the selected audio stream is a compressed audio stream output from the stream selector, using a corresponding decompression algorithm and to sampling frequency convert, multi-channel down mix and requantize the decoded audio data, according to the audio control signal.

According to a further aspect, there is provided a device for reproducing a DVD video/audio disk, comprising: a data receiver to receive data retrieved from the disk; a controller to analyze the data retrieved from the disk to discriminate a kind of the disk, the controller generating an audio control signal containing a video control signal, an audio coding mode, a sampling frequency, a number of channels and quantization information in case of the DVD video disk, or generating only the audio control signal in case of the DVD audio disk; a stream parser to separate the analyzed data output from the data receiver into video and audio data; a video decoder to decode the video data output from the stream parser; a video output to NTSC encode the decoded video data, and convert the encoded video data to an analog video signal; an audio decoder having a plurality of decoders, one of the decoders being selected according to the audio coding mode of the audio data to thereby decode the received audio data, including multi-channel mixing, sampling frequency converting and requantizing the audio data decoded, according to the audio control signal; and an audio output to convert the decoded audio data to an analog audio signal.

Preferably, the audio decoder comprises: a stream selector audio streams which form the audio data according to the audio coding mode; a linear PCM decoder to decode the selected audio stream is the selected audio stream is a linear PCM audio stream output from the stream selector, the linear PCM decoder sampling frequency converting, multi-channel down mixing and requantizing the decoded audio data according to the audio control signal; and a data decoder to decode the selected audio stream if the selected audio stream is a compressed audio stream output from the stream selector, using a corresponding decompression algorithm, the data decoder sampling frequency converting, multi-channel down mixing and requantizing the audio data decoded, according to the audio control signal.

According to yet another aspect there is provided a method for reproducing a DVD audio disk having information areas each having a title information management table recorded therein, and respective data areas each having sequential audio packs recorded therein, the method comprising the steps of: reading the title information management table for a title to be reproduced, and confirming an audio coding mode, sampling frequency, quantization bit number and channel number of the audio data recorded relating to the title; setting the audio decoding mode according to the confirmation; controlling the DVD audio disk in a playback mode, decoding the audio data according to the set audio decoding mode and performing sampling frequency conversion, multi-channel down mixing and requantization of the decoded data according to the audio coding mode to generate processed decoded audio data; and converting the processed decoded audio data to an analog signal.

According to another aspect there is provided a method for reproducing a DVD audio disk having information areas each having a title information management table recorded therein, and respective data areas each having sequential audio packs recorded therein, the method comprising the steps of: reading the title information management table of a title to be reproduced, and discriminating a kind of the DVD disk recorded; confirming video control information and audio control information containing a coding mode, sampling frequency, quantization bit number and channel number

of the audio data in case of the DVD video disk in the discrimination step, or confirming only the audio control information in case of the DVD audio disk; setting an audio decoding mode according to the confirmation in case of the DVD audio disk; controlling the DVD audio disk in a playback mode, decoding the audio data according to an audio coding mode and performing sampling frequency conversion, multi-channel down mixing and requantization of the decoded data according to the audio coding mode, to generate processed decoded data; and converting the processed decoded audio data to an analog signal.

According to a further aspect of the invention, there is provided a DVD audio disk to store audio data, comprising: information areas each storing a title information table related to the audio data; and respective data areas each storing the audio data having a sampling frequency of about 192KHz.

Preferably, the audio data has one of 16, 20 and 24 quantization bits. The audio data preferably has 24 quantization bits.

The title information table may include the sampling frequency, the number of quantization bits, a number of audio channels of the audio data, at least four bits to indicate the number of audio channels of the audio channels of the audio data and a maximum data transfer rate of the DVD audio disk, said digital audio data being sampled at the sampling frequency and quantized in the number of quantization bits with a number of channels of said digital audio data limited by said maximum data transfer rate.

The title information management table may further comprise compression ratio information of coding of the audio data, and the number of channels of the audio data may also be limited by the compression ratio information.

The audio data is preferably coded as pseudo-lossless psychoacoustic coding, which may be performed with a DTS coding system.

The audio data may be coded as linear pulse code modulated (PCM) coding.

Preferably, the maximum bit rate is approximately 10.08 Mbps and the number of channels is 13.

According to a still further aspect of the invention, there is provided a DVD audio disk comprising: information areas each storing an audio title having a title set management table with a plurality of audio stream attributes including an audio coding mode, a quantization bit number, a sampling frequency and a decoding algorithm information relating to a number of audio channels of audio data, respective data areas each including a plurality of audio packs having portions of said audio data corresponding to said decoding algorithm stored in said audio stream attribute and relating to the audio title; wherein the number of audio channels is limited by a data transmission velocity of the DVD audio disk, the sampling frequency and the quantization bit number.

Each of said audio packs may comprise: a pack header; a packet header; a sub-stream identification value; audio frame information; and one of said portions of said audio data. Each pack may also include stuffing frame information.

Said pack header is preferably 14 bytes, said packet header is 1 byte, said sub-stream identification value is 1 byte, said stuffing frame information is 1 byte, said audio frame information is 3 bytes and said one portion of said audio data is between 1 and 2013 bytes of linear pulse code modulated (PCM) data.

The pack header may be 14 bytes and each audio packet between 1 and 2021 bytes of pseudo-lossless psychoacoustic data.

The compression rate of the audio data is preferably between 1:1 and 5:1 for pseudo-lossless psychoacoustic coding.

The compression rate of the audio data is preferably 4:1 for the pseudo-lossless psychoacoustic coding.

Each title may have corresponding amounts of audio data having a sampling frequency of one of approximately 48, 96, and 192KHz, a quantization bit number of one of 16, 20, and 24.

The DVD audio disk preferably has a maximum data transmission rate of approximately 10.08Mbps.

Preferably, the title set management information table includes VTS\_MU\_AST\_ATR for information relating to up to eight audio channels of the audio data in a linear PCM mode, and information relating to additional audio channels of the audio data are stored in a reserved area of the information area after the VTS\_MU\_AST\_ATR.

In accordance with another aspect, there is provided a DVD audio disk to store audio data, comprising: information areas each storing a title set management information table related to the audio data; and respective data areas each storing the audio data in a digital theater system (DTS) mode, wherein the audio data has more than six audio channels.

In another aspect there is provided a DVD audio disk to store audio data, comprising: information areas each storing a title set management information table related to the audio data; and data areas each storing the audio data in a digital theater system (DTS) mode, wherein the audio data has a sampling frequency of approximately 192KHz.

If the audio coding mode is linear pulse code modulated (PCM) audio, a maximum number of said audio channels may be determined by the following Eq.1:

$$\text{Eq.1} \quad N = \frac{Mby}{Fs * Qb}$$

wherein  $F_s$  is the sampling frequency (HZ),  $Q_b$  is the quantization bit number,  $M_{by}$  is the maximum data transfer rate (Mbps) of the DVD-Audio disk, and  $N$  is the maximum number of said audio channels determined by the data transfer rate, sampling frequency and quantization bit number of the DVD-Audio disk.

In a further aspect, there is provided a DVD audio disk to store audio data, comprising: information areas each storing a title set management information table related to the audio data; and respective data areas each storing the audio data in a digital theater system (DTS) mode, wherein the audio data has a sampling frequency of approximately 192KHz.

If the audio coding mode is a compression coding system, a maximum number of said audio channels may be determined by the following Eq.2:

$$\text{Eq.2} \quad N = \frac{M_{by} * C_{cy}}{F_s * Q_b}$$

wherein  $F_s$  is the sampling frequency (HZ),  $Q_b$  is the quantization bit number,  $M_{by}$  is the maximum data transfer rate (Mbps) of the DVD-Audio disk,  $C_{cy}$  is a compression ratio according to a DTS compression coding system and  $N$  is the maximum number of said audio channels determined by data transfer rate, sampling frequency and quantization bit number of the DVD-Audio disk.

The title set management information table may have a plurality of audio stream attributes each having an audio coding mode, a quantization bit number, and a sampling frequency, wherein if the audio coding mode is linear pulse code modulated (PCM) audio, a maximum number of said audio channels is determined by the following Eq.1:

$$\text{Eq.1} \quad N = \frac{M_{by}}{F_s * Q_b}$$

wherein  $F_s$  is the sampling frequency (Hz),  $Q_b$  is the quantization bit number,  $M_{by}$  is the maximum data transfer rate (Mbps) of the DVD-Audio disk, and  $N$  is the maximum number of said audio channels determined by the data transfer rate, sampling frequency and quantization bit number of the DVD-Audio disk.

The title set management information table preferably has a plurality of audio stream attributes each having an audio coding mode, a quantization bit number, and a sampling frequency, wherein if the audio mode is a compression coding system, a maximum number of said audio channels is determined by the following Eq.2:

$$\text{Eq.2} \quad N = \frac{M_{by} * C_{cy}}{F_s * Q_b}$$

wherein  $F_s$  is the sampling frequency (Hz),  $Q_b$  is the quantization bit number,  $M_{by}$  is the maximum data transfer rate (Mbps) of the DVD-Audio disk,  $C_{cy}$  is a compression ratio according to a DTS compression coding system and  $N$  is the maximum number of said audio channels determined by data transfer rate, sampling frequency and quantization bit number of the DVD-Audio disk.

According to yet another aspect of the invention there is provided an apparatus to reproduce data from a DVD disk, comprising: a reading unit to read the data from the DVD disk; a system controller to generate an audio control signal including an audio coding mode, a sampling frequency, and number of channels, and quantization information of audio data of the data stored on the DVD disk; and an audio decoder including a plurality of decoders, wherein said system controller selects one of the plurality of decoders, based upon the audio control mode, to decode the audio data, including sampling frequency converting and requantizing the decoded audio data, according to the audio control signal.

The apparatus may further comprise a data receiver to correct errors in the read data; said one decoder to decode said corrected data, to generate the decode audio data; a sampling digital filter to filter the decoded data; and a digital/analog converter to convert the decoded data to an analog audio signal.

Said audio decoder preferably comprises: a stream selector to determine whether said corrected data is linear pulse code modulated (PCM) coded or compression coded; a linear PCM decoder to decode said linear PCM data to process data according to a linear PCM decoding method; a coding data decoder to decode said compression coded data to said processed data according to a corresponding compression decoding method; and a digital formatter to format said processed data as said decoded data.

Said system controller preferably discriminates whether the DVD disk is a DVD audio disk or a DVD video disk and controls reproduction of the DVD disk in a DVD video format if the DVD disk is a DVD video disk.

The apparatus may further comprise: a data receiver to correct errors in the read data; said audio decoder being an audio/video decoder to decode the corrected data; a video output circuit to convert the decoded data to an analog video signal, if the decoded data is indicative of video information and said system controller reproduces the data of

the DVD video disk in the DVD video format; a digital filter to filter the decoded data if the decoded data is indicative of audio information; and an audio output circuit to convert the filtered data to an analog audio signal.

Said video output circuit preferably encodes said decoded data in NTSC to generate said analog video data.

Said audio/video decoder may comprise: a stream parser to divide said corrected data which is indicative of the video information from the corrected data which is indicative of the audio information; a video decoder to decode the corrected data indicative of the video information, to generate the decoded data indicative of the video information; and an audio decoder to decode the corrected data indicative of the audio information, to generate the decoded information indicative of the audio information.

Said plurality of decoders may comprise: a linear PCM decoder; a Dolby AC-3 decoder; a coding data decoder; and an MPEG decoder; wherein said system controller drives the corresponding one of said linear PCM decoder, Dolby AC-3 decoder, coding data decoder, and MPEG decoder, to decode the corrected data indicative of the audio information based upon a coding format of the corrected data indicative of the audio information.

The audio data preferably has a sampling frequency of 192KHz.

The audio data is preferably in a digital theater system (DTS) mode, and has more than six audio channels. In the DTS mode, the audio data preferably has a sampling frequency of at least approximately 96KHz and, most preferably, has a sampling frequency of approximately 192KHz.

In accordance with yet another aspect, there is provided an apparatus to reproduce data from a disk which is a DVD audio disk and from a DVD video disk, comprising: a reading unit to read the data from the disk; a system controller to distinguish the disk as the DVD audio disk or the DVD video disk; and an audio decoder including a plurality of decoders, wherein said system controller selects one of the plurality of decoders, based upon an audio control mode of the data and the determination of whether the disk is a DVD video disk or a DVD audio disk, to decode the data if the data is audio data.

The apparatus may include a video decoder to decode the data if the disk is a DVD video disk and the data is video data.

According to a further aspect, there is provided a method for reproducing data from a DVD disk, comprising the steps of: (a) reading a title set management table of a title to be reproduced; (b) reading VTSM\_AST\_ATR of the title set management table to determine a coding mode of the data; and (c) decoding the data based upon the determined coding mode.

Said step (b) may further comprise the step (bl) of reading a sampling frequency and number of quantization bits; and said step (c) may further comprise the step (cl) of decoding the data based upon the sampling frequency and the number of quantization bits.

The sampling frequency is preferably 192KHz, the data is audio data, and said step (cl) decodes the audio data of 192KHz in accordance with the decoding algorithm and the number of quantization bits.

There may be included the step of discriminating whether the DVD disk is a DVD video disk or a DVD audio disk based upon the coding mode, sampling frequency and number of quantization bits, wherein said step (c1) further comprises the step of decoding the data based upon whether DVD disk is the DVD video disk or the DVD audio disk.

The method may further comprise the steps of: (d) determining whether there is a menu in the title set management table; (e) determining whether the menu is to be played back; and (f) reproducing the menu to be played back.

Said step (c) may comprise the steps of: (c1) determining whether the coding mode is a linear pulse code modulated (PCM) mode; (c2) determining whether a channel number of the data is greater than eight or has a sampling frequency of approximately 192KHz if the coding mode is the linear PCM mode, and determining the DVD disk to be a DVD audio disk if the channel number is greater than 8 or has the sampling frequency of 192KHz; (c3) determining whether the coding mode is a digital theater system (DTS) mode if the coding mode is not the linear PCM mode or said step (c2) determines that the channel number is not greater than eight or the sampling frequency is not approximately 192KHz; and (c4) determining whether the channel number is greater than 6 or the sampling frequency is at least 96KHz if the coding mode is the DTS mode, and determining the DVD disk to be the DVD audio disk if in the DTS mode the channel number is greater than six or the sampling frequency is at least 96KHz, otherwise determining the DVD disk to be a DVD video disk.

Said step (c) may comprise the steps of:

determining whether a channel number of the data is greater than eight or has a sampling frequency of approximately 192KHz if the coding mode is a linear pulse code modulated (PCM) mode, and determining the DVD disk to be a DVD audio disk if the channel number is greater than 8 or has the sampling frequency of 192KHz in the linear PCM mode;

determining whether the channel number is greater than 6 or the sampling frequency is at least 96KHz if the coding mode is a digital theater system (DTS) mode, and determining the DVD disk to be the DVD audio disk if in the DTS mode the channel number is greater than six or the sampling frequency is at least 96KHz; and

otherwise determining the DVD disk to be a DVD video disk.

The method may include steps of:

5 (c1) muting an analog audio output of the decoded data; (c2) selecting a digital filter program according to the sampling frequency; (c3) determining a length of the decoded data; (c4) initializing a deemphasis flag; (c5) starting an interrupt; and (c6) releasing the mute of the analog audio output.

There may be included the steps of: determining an operation status of the decoding of the data; and interrupting the decoding if an abnormality on the operation status is determined, and then performing a cure algorithm to remove the abnormality.

10 The method may comprise the steps of: performing 32-fold oversampling digital filtering of the decoded data if the sampling frequency is 48KHz, 16-fold oversampling of the decoded data if the sampling frequency is 96KHz, and performing 8-fold oversampling digital filtering of the decoded data if the sampling frequency is 192KHz.

For a better understanding of the invention, and to show how embodiments of the same may be carried into effect, reference will now be made, by way of example, to the accompanying diagrammatic drawings, in which:

The present invention proposes a DVD audio disk and a device and method for reproducing it. According to the VTSM\_MAT of the DVD audio disk of the embodiment of the present invention, the audio information is changed in the VTSM\_MAT of the DVD video disk shown in table 1. With the DVD audio disk of the present invention, VTSM\_AST\_ATR of RBP 260-267, VTS\_AST\_ATRT of RBP 516-579, and the information of the reserved area of RBP 984-2047 are changed in the VTSM\_MAT shown in tables 1a and 1b.

The audio coding mode of VTSM\_AST\_ATR and VTS\_AST\_ATRT stores the coding information of the audio data recorded on the disk. In the preferred embodiment of the present invention, there is presented an example of recording audio data on the DVD audio disk in the linear PCM mode or pseudo-lossless psychoacoustic coding mode. In this embodiment, it is assumed that the psychoacoustic coding mode uses the DTS coding mode. Here, the DTS coding mode can be used optionally. If b63-b61 is "110b", this designates the DTS audio coding mode.

Explaining the change of VTSM\_AST\_ATR, the data pattern and definition of b55-b48 are changed, as shown in Figure 11. In b55-b48 of VTSM AST ATR shown in Figure 2, the reserved bits of b51 are absorbed to the audio channel bit which is the number of audio channels.

According to the definition changed in Figure 11, the audio sampling frequency  $f_s$  is changed as shown in table 17.

[ Table 17 ]

b55-b54	$f_s$
00b	48KHz
01b	96KHz
10b	192KHz
11b	Reserved

The number of audio channels is changed as in tables 18a and 18b.

[ Table 18a ]

b51-b48	Number of Audio Channels
0000b	1ch (mono)
0001b	2ch (stereo)
0010b	3ch (multichannel)
0011b	4ch (multichannel)
0100b	5ch (multichannel)

[ Table 18b ]

0101b	6ch (multichannel)
0110b	7ch (multichannel)
0111b	8ch (multichannel)

[ Table 18b ] (continued)

1000b	9ch (multichannel)
1001b	10ch (multichannel)
1010b	11ch (multichannel)
1011b	12ch (multichannel)
1100b	13ch (multichannel)
1101b	14ch (multichannel)
1110b	15ch (multichannel)
1111b	16ch (multichannel)

With VTS\_AST\_ATRT, the data pattern and definition of b55-b48 are changed as in Figure 12. In VTS\_AST\_ATRT of Figure 3, the reserved bits of b51 are absorbed to the number of audio channels. According to the definition changed in Figure 11, the audio sampling frequency  $f_s$  is changed as in table 17, and the number of audio channels is changed as in tables 18a and 18b.

To VTS\_MU\_AST\_ATR, the information shown in Figures 13a and 13b is added. The VTS\_MU\_AST\_ATR offers information to the linear PCM audio only to eight channels but not thereabove. Therefore, if the linear PCM data is written, maximum 13 channels are available so that information from ninth channel to the thirteenth channel is written in the reserved area after VTS\_MU\_AST\_ATR. VTS\_MU\_AST\_ATR\_EXT is composed of VTS\_MU\_AST\_EXT (1) shown in Figure 13a and VTS\_MU\_AST\_ATR\_EXT (2) shown in Figure 13b, like VTS\_MU\_AST\_ATR.

The format of the DVD audio disk having the VTSI\_MAT changed as above is divided into the linear PCM area and pseudo-lossless psychoacoustic coded data.

First of all, in the DVD audio disk of the linear PCM area, data is recorded in the linear PCM mode. The sampling frequency is 48, 96, and 192 KHz. The number of quantization bits is 16, 20, and 24 bits. The number of recording channels is from one to the maximum number the bit rate permits. The number of recording channels is determined with the following equation 1.

$$N = \frac{Mbr}{F_s * Qb} \quad (1)$$

$F_s$ : sampling frequency (Hz); 48, 96, 192KHz

$Qb$ : number of quantization bits; 16, 20, 24 bits

$Mbr$ : maximum data transmission rate (Mbps) of DVD disk; 10.08Mbps

$N$ : maximum number of channels recordable determined by the data transmission rate, sampling frequency, and the number of quantization bits of the DVD disk.

The number of channels determined by equation 1 is shown in table 19.

[ Table 19 ]

Sampling Frequency	Number of Quantization Bits	Maximum Number of Channels
48KHz	16 bit	13 channel
48KHz	20 bit	10 channel
48KHz	24 bit	8 channel
96KHz	16 bit	6 channel
96KHz	20 bit	5 channel
96KHz	24 bit	4 channel
192KHz	16 bit	3 channel
192KHz	20 bit	2 channel
192KHz	24 bit	2 channel

The data structure of the DVD audio disk of the present invention is based on the MPEG2 system layer. In case of the linear PCM of the present invention, the audio pack is made as in Figure 14. The linear PCM audio pack shown in Figure 14 has the same structure as that in Figure 5a. The audio pack has 14 bytes of pack header and maximum 2021 bytes of linear PCM packet. The pack header of Figure 14 conforms to the standards of the MPEG2 system layer.

The structure of the linear PCM audio packet is on basis of the standards of the MPEG2 system layer. The audio packet of the linear PCM has the structure shown in table 10 and table 20.

[ Table 20 ]

				Audio
data area (Linear PCM)				
In table 20, Note 1 - Note 10 are as follows.				
Note 1: *** indicates the decoding audio data stream number.				
Note 2: "number_of_frame_headers" indicates the number of audio frames containing the first byte within the corresponding audio packet.				
Note 3: The access unit is audio frame. The first_access_unit indicates the first audio frame containing the first byte within the corresponding audio packet.				
Note 4: "audio_emphasis_flag" indicates the state of emphasis. If the audio sampling frequency is 96, 192 KHz, this should be represented as "emphasis off". The emphasis is applied from the sample of the first access unit.				
0b: emphasis off				
1b: emphasis on				
Note 5: "audio mute flag" indicates the state of mute if all the data of the audio frame is zero. Mute is applied from the first sample of the first access unit.				
0b: mute off				
1b: mute on				
Note 6: "audio frame number" is the number of ground of audio frame GOF of the first access unit of the audio packet. This number covers from 0 to 19.				
Note 7: "quantization_word_length" is the number of bits used in the quantization of audio sample.				
00b: 16 bits				
01b: 20 bits				
10b: 24 bits				
11b: reserved				
Note 8: "audio_sampling_frequency" is the sampling frequency used in the sampling of the audio sample.				
00b: 48KHz				
10b: 192KHz				
01b: 96KHz				
11b: reserved

If the number of sample is smaller than that in tables 21a and 21b, the length of the padding packet is increased to fit the length of the pack. The samples coincide with the packet boundary. In other words, all the audio packets start from the first byte of  $S_{2n}$ . The number of the audio samples is always even within one packet.

From now on, the DVD audio disk that records the psychoacoustic coded audio data will be described.

In case of recording the audio data of linear PCM and if 48KHz of sampling frequency and 16 bits of quantizer are used as in table 19, 13 channels are available so that the audio data can be written in up to 10 channels that are required for multi-channel music. However, in case of 192KHz of sampling frequency and 24 bits of quantizer, maximum two channels of audio data are written as in table 19, which cannot meet the requirement of multi-channel audio. If sampling is performed by using many bits at a high sampling frequency, it is difficult to implement the function of multi-channel audio. For this, lossless coding or pseudo-lossless psychoacoustic coding is used. But, it is hard to expect much effect in implementation of multi-channel because the compression rate of the lossless coding is 2:1 in most cases.

In this embodiment, it is assumed that the pseudo-lossless psychoacoustic coding method uses DTS coding mode which has a compression rate of 4:1. The DTS coding mode is able to contain a sufficient number of channels without any deterioration of sound quality. For instance, DTS enables coding for a high specification of 192KHz and 14 bits, unlike other currently presented coding algorithms, and minimizes the deterioration of sound quality rather than minimizing bit rate. The sampling frequency is 48, 96, and 192 KHz, the number of quantization bit is 16, 20, and 24 bits, and the number of recording channels ranges from one to a maximum number allowed by the particular coding mode and bit rate. The number of recording channels can be determined by the following equation 2.

$$N = \frac{Mbr * Ccr}{Fs * Qb} \quad (2)$$

Fs: sampling frequency (Hz); 48KHz, 96KHz, 192KHz

Qb: number of quantization bits; 16 bits, 20 bits, 24 bits

Mbr: maximum data transmission rate (10.08Mbps) of DVD disk

Ccr: compression ratio in accordance with a compressive coding mode

N: maximum number of channels recordable determined by the data transmission rate, sampling frequency, and the number of quantization bits, and compression ratio of the DVD disk. Here, the coding mode is assumed to use the DTS having a 4:1 compression rate. In this case the number of channels determined by equation 2 is shown in table 22.

[Table 22]

Sampling Frequency	Number of Quantization Bits	Maximum Number of Channels
48KHz	16 bit	52 channel
48KHz	20 bit	42 channel
48KHz	24 bit	35 channel
96KHz	16 bit	26 channel
96KHz	20 bit	21 channel
96KHz	24 bit	17 channel
192KHz	16 bit	13 channel
192KHz	20 bit	10 channel
192KHz	24 bit	8 channel

As stated above, the structure of the DVD audio disk of the present invention is based upon the MPEG2 system layer, and therefore the audio pack compressed is made as in Figure 15. The audio pack compressed is made to have 14 bytes of pack header and maximum 2021 bytes of audio packet compressed. In Figure 14, the pack header conforms to the standards of the MPEG2 system layer.

The structure of the audio packet compressed is also based upon the standards of the MPEG2 system layer. The audio packet coded is structured as in tables 10 and 23.

[ Table 23 ]

Field	Number of bits	Number of Bytes	Value	Comment
sub_stream_id	8	1	&&&& &***b	Note 1
number of frame_headers	8	1	Provider defined	Note 2
first access _unit_pointer	16	2	Provider defined	Note 3
DTS audio data area				
In the above table 23, Note 1 - Note 3 are as follows.				
Note 1: "sub_stream_id" is different according to the coding mode. If the coding mode is DTS, it becomes *1000 1***b". In the sub_stream_id, *** is the number of the decoding audio stream.				
Note 2: "number of frame headers" indicates the number of audio frame containing the first byte within the corresponding audio packet.				
Note 3: The access unit is audio frame. First_access unit indicates the first audio frame containing the first byte within the corresponding audio packet.				

The DVD audio disk of the compressive coding mode has the following specifications. The number of channels enabling compression is over eight channels. The sampling frequency is 48, 96 or 192KHz. The number of quantization bits is 16, 20, or 24 bits. The compression rate is available from 1:1 to 5:1. Down mixing, dynamic range control, and time stamp are enabled. Finally, the excellency of sound quality is actually recognized.

A device for reproducing the DVD audio disk can be formed independently. Or it can be connected to the DVD video reproducing device. In this embodiment, the DVD audio disk reproducing device is first explained, and then the reproducing device to which the DVD audio disk reproducing device is added.

The DVD audio disk reproducing device is shown in Figure 16. System controller 111 controls the overall operation of the DVD audio disk reproducing device, interfacing the user. System controller 111 analyzes the VTSI\_MAT, audio pack and packet headers recorded on the DVD audio disk, in order to perform the overall operation of reproducing the audio signal. Pickup 112 performs the function of reading the data recorded on the DVD audio disk. Servo controller 113 controls the driving of pickup 112 under the control of system controller 111, performing various servo functions. Data receiver 114 performs the error analysis and correction of the audio data output from pickup 112. Data receiver 114 contains an error correction circuit (ECC). Audio decoder 115 sends the audio information output from data receiver 114 to system controller 111, and decodes the audio data received under the control of system controller 111.

Audio decoder 115 has a configuration of decoding the linear PCM audio data and compressed audio data in order to decode the audio data in accordance with the embodiment of the present invention. This configuration is shown in Figure 17.

Referring to Figure 17, input data buffer 211 receives and stores the audio data output from data receiver 114. Stream selector 212 selectively outputs the audio data stream output from input data buffer 211 under the control of system controller 111. Linear PCM decoder 213 receives the linear audio data output from stream selector 212, and decodes and outputs it as the original audio data. Pseudo-lossless psychoacoustic decoder 214 receives the compressed data output from stream selector 212, and decodes and outputs it as the original audio data. Output data buffer 215 stores and outputs the audio data output from decoders 213 and 214. Digital audio formatter 216 changes the audio data output from decoders 213 and 214 to the format designated by system controller 111. Timing controller 210 controls system controller 111 so as to generate timing control signals for controlling the operation of the respective components of audio decoder 115.

High-bit high-sampling digital filter 116 receives the audio data output from audio decoder 115, and digitally filters the audio data according to the control signal of system controller 111. High-performance digital to analog converters and analog audio circuitry 117 converts the audio data output from high-bit high-sampling digital filter 116 into an analog signal.

Referring to Figures 16 and 17, data receiver 114 sends the audio data reproduced from the DVD audio disk to audio decoder 115 via pickup 112. The audio data reproduced is stored sequentially to the input data buffer 211 of audio decoder 115. The stream selector 212 selectively outputs the data stored in input data buffer 211 to the corresponding decoder 213 or 214. When the system controller 111 requests audio data decoding of linear PCM, stream selector 212 transmits the audio data stored in input data buffer 211 to linear PCM decoder 213. If system controller 111 requests the decoding of the compressed data, stream selector 212 transmits the audio data stored in input data buffer 211 to decoder 214.

Explaining the decoding of the linear PCM audio data, linear PCM decoder 213 performs multi-channel down mixing, sampling frequency conversion, and requantization of the input signal. For instance, if the data output from stream selector 212 is 8-channel data, and it is required to be converted to two-channel data in its output, linear PCM decoder 213 makes a desired number of channels by performing multi-channel down mixing. If the input data is sampled at 192KHz and the system controller 111 requires the output of sampling data of 96KHz, linear PCM decoder 213 performs the sampling frequency conversion, and converts it to audio data having a required sampling frequency. If the audio data input is 24-bit quantization data and the system controller 111 requires 16-bit quantization data output, linear PCM decoder 213 performs requantization, and thus generates a desired number of bits of output audio data.

Explaining the decoding of the compressed audio data, decoder 214 decodes the compressed audio data by using the corresponding algorithm under the control of system controller 111. Here, the form of audio data output from decoder 214 is designated by system controller 111. In the embodiment of the present invention, decoder 214 can become the DTS decoder. The decoder 214 performs multi-channel down mixing, sampling frequency conversion, and requantization of input signal, as well as the decoding of a designated algorithm.

The audio data decoded and output from decoders 213 and 214 is transmitted to output data buffer 215 and digital audio formatter 216. Then, output data buffer 215 stores the input decoded audio data, and outputs it in sync with the control signal output from timing controller 210. Digital audio formatter 216 formats the decoded audio data in accordance with the transmission format between the digital appliances, and then outputs the formatted data in sync with the control signal output from timing controller 210. Here, the audio data externally output can be output to audio/video device or computer having the same transmission format.

The decoded audio data output from audio decoder 115 is digitally filtered by high-bit high-sampling digital filter 116 and then output, and high-performance digital to analog converters and analog audio circuitry 117 converts the audio data output from high-bit high-sampling digital filter 116. Here, filter 116 is formed with digital filters, removing noise components other than the audio signal band. In order to process the audio data sampled at 192KHz and quantized with 24 bits, high-bit high-sampling digital filter 116 requires a filter coefficient having a resolution and the number of taps far greater than those of the digital filters used in DVD or CD. If a D/A converter of 96 or 192KHz is generally used, high-bit high-sampling digital filter 116 may be included in the D/A converter. The high-performance digital to analog converters and analog audio circuitry 117 is formed with D/A converters, and converts the audio data whose noise is removed by high-bit high-sampling digital filter 116 to an analog audio signal.

The configuration of the device for reproducing both the DVD video and audio disks is shown in Figure 18. System controller 311 controls the overall operation of this reproducing device, interfacing the user. System controller 111 analyzes the VTSI\_MAT, audio pack and packet headers recorded on the DVD video disk and DVD audio disk, discriminates the kind of disks, and performs the overall control of the reproduction of the video or audio signal according to the discrimination result. Pickup 312 performs the function of reading the data recorded on the DVD disk. Servo controller 313 controls the driving of pickup 312 under the control of system controller 311, performing the various servo functions. Data receiver 314 performs error analysis and correction of the audio data output from pickup 312.

Data receiver 314 contains ECC. Audio/video decoder 315 transmits the information output from data receiver 314 to system controller 311, and decodes the audio/video data received, under the control of system controller 311.

Audio/video decoder 315 has a configuration of decoding the video/audio data, which is shown in Figure 19. Referring to Figure 19, input data buffer 411 receives and stores the audio/video data output from data receiver 314. Stream parser 412 selectively outputs the audio/video data stream output from input data buffer 411 under the control of system controller 311. Audio decoder 413 receives the audio data selectively output from stream parser 412, and decodes the audio data in a mode selected by the control data output from system controller 311. Decoding audio output 414 outputs the audio data decoded and output from audio decoder 413. Video decoder 415 receives the video data selectively output from stream parser 412, and decodes the video data in a corresponding mode by the control data output from the system controller 311. Decoding video output 416 outputs the video data decoded and output from video decoder 415. Timing controller 410 generates timing control signals for controlling the operation of the respective components of the audio/video decoder 315.

In Figure 19, audio decoder 413 should have decoding devices respectively corresponding to the linear PCM, MPEG, AC-3 and compressive coding modes. Here, the linear PCM and compressive coding modes must further have a configuration for reproducing the audio data recorded in the disk of the present invention. In other words, this invention has decoders for reproducing audio data in accordance with the sampling frequency, quantization bit, and audio channel number of the embodiment, and a stream selector for distributing the audio data corresponding to the respective decoders.

High-bit high-sampling digital filter 316 receives audio data output from audio/video decoder 315, and digitally filters the audio data input, according to the control signal of system controller 311. High performance digital to analog converters and analog audio circuitry 317 performs analog conversion of the audio data output from high-bit high-sampling digital filter 316. NTSC encoder video digital to analog converter's analog video circuitry 318 NTSC codes the video data output from video decoder 315, and converts it to analog signal.

Referring to Figures 18 and 19, the reproduced data of the disk output from pickup 312 is transmitted to data receiver 314, and data receiver 314 error corrects and analyzes the data received, which is then transmitted to audio/video decoder 315. The data output from data receiver 314 is applied and stored in input data buffer 411 of audio/video decoder 315. System parser 412 selects a required stream according to the control data of system controller 311, analyzes the input data, transmits the video data to video decoder 415, and transmits the audio data to audio decoder 413.

Audio decoder 413 deforms and outputs the audio data output from stream parser 412 according to system controller 311. Audio decoder 413 must include the audio decoding of the DVD video disk and the audio decoding of the DVD audio disk.

Video decoder 415 decodes, deforms and outputs the input video data according to the system controller 311. The video data deformation of video decoder 415 means video signal processing, such as sub\_title process or pan\_scan.

The decoded audio/video data output from audio decoder 413 and video decoder 415 are output to decoding audio output 414 and decoding video output 416. Then, outputs 414 and 416 store the decoded data input, and output it in sync with the timing control signal output from timing controller 410. Here, the decoding audio output 414 externally transmits the digital audio data formatted in accordance with the transmission format between the digital appliances. The audio data output from decoding audio output 414 is transmitted to other audio/video device or computer.

The audio/video decoder 315 of the reproducing device shown in Figure 18 conforms to the standards of the DVD video in processing the video signal, and processes the algorithm of the present invention and the algorithm in accordance with the standards of the DVD video in processing audio signal. Audio decoder 413 contains the linear PCM and DTS algorithm among the audio standards in the DVD video disk so that playback must be enabled even in case the DVD video disk is inserted or in case that the DVD audio disk of the present invention is inserted.

Here, the audio algorithm required in decoding of the DVD video disk is linear PCM decoding (1) + AC-3 decoding + MPEG decoding. The audio algorithm required in decoding of the DVD audio disk of the present invention is linear PCM decoding (2) + pseudo-lossless psychoacoustic decoding. Therefore, the linear PCM algorithm of the DVD video disk is contained in the linear PCM algorithm of the present invention. The audio data decoding algorithm used in the DVD video/audio disk reproducing device must contain the functions of the equation 3, and is performed in audio decoder 413.

Equation 3

$$\begin{aligned} \text{Audio decoder} &= \text{linear PCM decoder (2) + pseudo-} \\ &\text{lossless psychoacoustic decoder + AC-3 decoder + MPEG} \\ &\text{decoder} \end{aligned}$$

The reproducing device having the configuration of Figure 16 or 18 analyzes the information of VTSM\_MAT stored in the lead-in area of the disk, to thereby reproduce the audio of the title corresponding to the VTSM\_MAT. In this embodiment of the present invention the DVD-audio disk is assumed.

Figure 20 shows the flow chart of analyzing and setting the information of VTSM\_MAT in system controller 111. Referring to Figure 20, system controller 111 reads out VTSM\_MAT of a title intended to reproduce like tables 1 and 2 in the lead-in area of the disk. System controller 111 analyzes VTSM\_MAT read in step 513, and checks whether there is a menu, and a command loaded in the disk or the user requires playback.

If the menu is required to playback, system controller 111 reads VTSM\_AST\_ATR shown in Figure 11 from the information of VTSM\_MAT, and confirms an algorithm necessary in step 515. System controller 111 reads out the audio coding mode of VTSM\_AST\_ATR, confirms the corresponding audio coding mode, and sets the audio decoder 115 in order to perform the algorithm of the corresponding audio coding mode in step 517. Here, the functions that must be set in audio decoder 115 are quantization/DRC information, sampling frequency fs, and audio channel number. After setting audio decoder 115, system controller 111 reproduces the menu of the corresponding title while performing steps 519 and 521. Such procedure is a process that reproduces the menu of the title.

If the playback of menu is not required in step 513 or the playback of menu of the title is finished in step 521, system controller 111 progresses to step 523 so as to confirm the information of VTS\_AST\_ATR shown in Figure 12 from the information of VTSM\_MAT. Here, system controller 111 confirms the audio coding mode of VTS\_AST\_ATR shown in Figure 12, and thus the algorithm of the corresponding audio data. System controller 111 confirms the quantization information, sampling frequency and channel number of VTS\_AST\_ATR in step 525, to thereby set audio decoder 115. In step 527, audio decoder 115 is controlled so that the audio packets of the corresponding title are decoded.

Figure 21 shows the flow chart of setting audio decoder 115 in steps 517 and 525 of Figure 20. Referring to Figure 21, an operation will be described in which system controller 111 sets audio decoder 115 according to VTS\_AST\_ATR and VTSM\_AST\_ATR. Here, the audio coding mode is assumed as linear PCM audio or DTS coding audio.

First, system controller 111 analyzes the audio coding mode of VTS\_AST\_ATR and VTSM\_AST\_ATR in step 611, to thereby check the coding mode of the audio data stored in the DVD audio disk. Here, if the audio algorithm is linear PCM, system controller 111 senses this in step 611, and proceeds in steps 613 to check whether the number of channels of the linear PCM audio data is greater than 8 or the sampling frequency is 192KHz in step 613. In this case, the audio decoder 115 is set to perform the corresponding algorithm and uses output data buffer 215 in correspondence with the sampling frequency in step 621 if the number of channels of the linear PCM audio data is greater than eight or the sampling frequency is 192KHz because the disk is a new format of DVD audio disk in accordance with the embodiment of the present invention.

If the number of audio channels is not greater than 8 and the sampling frequency is below 192KHz in step 613, the audio has the same format as that of the DVD video disk so that system controller 111 sets audio decoder 115 and output data buffer 215 in correspondence with the sampling frequency in order to perform the corresponding algorithm in step 619.

If the audio algorithm is not linear PCM in step 611, step 615 checks whether the audio algorithm of VTS\_AST\_ATR and VTSM\_AST\_ATR is DTS or not. Here, if the disk is DTS audio, it is checked in step 617 whether the number of audio channels is greater than 6 or the sampling frequency is 96 or 192KHz. Here, if so, step 621 is carried out because this disk is a new format of DVD audio disk. However, if the number of channels of the DTS data is below 6 and the sampling frequency is 48KHz, step 619 progresses because the disk has the same audio format as that of the DVD video disk.

After setting the audio decoder 115, system controller 111 performs the procedure of Figure 22, initializing the high-bit high-sampling digital filter 116 and the high-performance digital to analog converters and analog audio circuitry 117. System controller 111 controls the high-performance digital to analog converters and analog audio circuitry 117 in step 711 to mute the analog audio output. In step 713, the high-bit high-sampling digital filter 116 is controlled to select a digital filter program according to the sampling frequency, and in step 715, the length of an input block to be filtered is determined. System controller 111 initializes the deemphasis flag in step 717, and operates the program in step 719 to start the interrupt. Then, the system controller 111 controls the audio output 117 in step 721, to release the analog audio output mute.

After setting the audio decoder according to the VTSM\_MAT information through the procedure of Figures 20, 21 and 22, the system controller 111 analyzes the audio pack stored in the corresponding data area of the disk, and reproduces the audio data stored in the disk, as in Figure 23.

System controller 111 controls the audio decoder 115 set in step 811 to instruct the decoding start. In step 813, the system selector 212 is controlled to transmit the received audio data to decoder 213 or 214 having a corresponding audio algorithm. Then, the corresponding decoder 213 or 214 decodes the audio data of the corresponding algorithm. Here, the system controller 111 checks the operation status of decoder 213 or 214 in step 815. If there occurs decoding trouble, step 821 progresses to control the currently operating decoder to interrupt the decoding operation. Then, the

system selector 212 is controlled to interrupt the transmission of data, drives a cure algorithm in accordance with the trouble, and returns to step 811.

If the currently operating decoder normally runs in step 815, step 817 externally outputs the decoded audio data through the output data buffer 215 or the digital audio formatter 216 in step 817. In step 819, the operation status of the audio decoder 115 is checked. If there occurs a decoding trouble, step 821 progresses, or if not, the step returns to decode the next audio data.

If the decoding of the audio stream is finished in the audio decoder 115, the system controller 111 controls high-bit high-sampling digital filter 116 and high-performance digital to analog converters and analog audio circuitry 117 through the procedure of Figure 24, and converts the decoded audio data to an analog audio signal. If the decoded audio data is output from audio decoder 115, system controller 111 controls high-bit high-sampling digital filter 116 through steps 911-917, and performs digital filtering corresponding to the sampling frequency. First of all, system controller 111 checks the sampling frequency, and performs the oversampling digital filtering according to 48, 96, or 192KHz. Here, if the sampling frequency is 48KHz, 32-fold oversampling digital filtering is performed. If the frequency is 96KHz, 16-fold oversampling digital filtering is performed. In case of 192KHz, 8-fold oversampling digital filtering is performed.

After performing the oversampling digital filtering corresponding to the sampling frequency, system controller 111 controls high-performance digital to analog converters and analog audio circuitry 117 in step 919 to convert the digitally filtered audio signal to an analog audio signal, and in step 921, the converted analog audio signal is lowpass filtered and buffered in the audio band.

As described above, the DVD audio disk of the present invention is capable of recording maximum 192KHz of sampling frequency and 24 bits of quantized audio data, as well as greatly extending the number of audio channels. Therefore, if the audio data recorded on the DVD audio disk is reproduced faithfully, a good-quality audio signal is reproduced, which corresponds to multi-channel music. The number of channels recordable limited by the data transmission velocity of a disk used, the sampling frequency of signal, and the number of quantization bits of the sample can be rendered multiple because the audio signal is recorded a high sampling frequency and many quantization bits using a coding algorithm.

A general DVD video reproducing device has a specification not coming up to that of the DVD audio disk so that a DVD audio reproducing device capable of reproducing 192KHz and 24 bits of data may be disposed to the DVD video reproducing device according to its own performance. Here, the DVD audio reproducing device comprises an audio decoder that performs decimation and requantization, and can reproduce multi-channel music, using a decoding algorithm in accordance with the coding mode recorded on the DVD audio disk.

Therefore, it should be understood that the present invention is not limited to the particular embodiment disclosed herein as the best mode contemplated for carrying out the present invention, but rather that the present invention is not limited to the specific embodiments described in this specification except as defined in the appended claims.

The reader's attention is directed to all papers and documents which are filed concurrently with or previous to this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, may be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive.

Each feature disclosed in this specification (including any accompanying claims, abstract and drawings), may be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features.

The invention is not restricted to the details of the foregoing embodiment(s). The invention extends to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any novel one, or any novel combination, of the steps of any method or process so disclosed.

## Claims

1. A DVD audio disk to store audio data, comprising:

information areas each storing an audio title information management table; and

respective data areas each storing audio packs of a linear pulse code modulated (PCM) mode;

wherein the audio title information management table includes a first, second or third number of quantization bits corresponding to the audio data, a first, second or third sampling frequency corresponding to the audio data, and information relative to a number of audio channels of the audio data, and each audio pack including audio packets having the first, second or third number of quantization bits, the first, second or third sampling frequency and the information relative to the number of channels which are recorded in the audio title information management table, and the audio packets further containing corresponding portions of the audio data.

2. A DVD audio disk as claimed in claim 1, wherein the first, second and third quantization number of bits are 16, 20, and 24 bits, respectively, the first, second and third sampling frequencies are 48, 96, and 192KHz, respectively, a maximum number of the audio channels being 13, and the number of channels being determined by the following equation:

$$N = \frac{Mbr}{F_s * Qb}$$

Wherein,

F<sub>s</sub> is the sampling frequency (Hz) of the audio data,  
Q<sub>b</sub> is the number of quantization bits of the audio data,  
Mbr is a maximum data transmission rate (Mbps) of the DVD audio disk, and  
N is a maximum number of recordable channels as determined by the maximum data transmission rate, sampling frequency, and the number of quantization bits of the DVD disk.

3. A DVD audio disk to store audio data, comprising:

information areas each storing a title information management table; and

respective data areas each storing a pseudo-lossless psychoacoustic coding mode;

wherein the title information management table includes a first, second or third number of quantization bits corresponding to the audio data, a first, second or third sampling frequency corresponding to the audio data, and information relative to a number of audio channels of the audio data, and each audio pack including audio packets having the first, second or third number of quantization bits, the first, second or third sampling frequency, and the information relative to the number of channels which are recorded in the title information management table, and the packets further containing corresponding portions of the audio data.

4. A DVD audio disk as claimed in claim 1, wherein the pseudo-lossless psychoacoustic coding mode uses a Digital Theatre System (DTS) compressive coding mode, the first, second and third numbers of quantization bits of the audio data prior to compression are 16, 20, and 24 bits, respectively, the first, second and third sampling frequencies are 48, 96, and 192 KHz, respectively, a maximum number of the audio channels being 16 and, the number of channels being determined by the following equation:

$$N = \frac{Mbr * Ccr}{F_s * Qb}$$

Wherein,

F<sub>s</sub> is the sampling frequency (Hz), of the audio data, Q<sub>b</sub>: number of quantization bits of the audio data,  
Mbr is a maximum data transmission rate (Mbps) of the DVD audio disk.  
Ccr is a compression ratio in accordance with the DTS compressive coding mode, and N is a maximum number of recordable channels as determined by the data transmission rate, the sampling frequency, the number of quantization bits, and the compression ratio of the DVD audio disk.

5. A DVD audio disk to store audio data, comprising:

information areas each storing a title information management table; and

respective data areas each storing sequential audio packs; wherein the DVD audio disk conforms to the

MPEG2 system layer standards;

wherein the title information management table has an audio stream attribute area which includes an audio coding mode, a number of quantization bits, and a sampling frequency related to the audio packs, and information related to the number of audio channels,

each of the audio packs includes a pack header and audio packets;

each of the audio packets includes a packet header, sub-stream ID, audio frame information, audio data information, and a portion of the audio data; and

the number of channels of audio data received is determined by the following equation:

$$N = \frac{Mbr * Ccr}{Fs * Qb}$$

and wherein  $F_s$  is the sampling frequency (Hz), having a value of one of 48KHz, 96KHz and 192KHz  $Q_b$  is the number of quantization bits having a value of one of 16 bits, 20 bits, and 24 bits.  $Mbr$  is a maximum data transmission rate (10.08Mbps) of the DVD audio disk.

$Ccr$  is a compression ratio in accordance with a compressive coding mode, and

$N$  is a maximum number of recordable channels as determined by the data transmission rate, the sampling frequency, the number of quantization bits, and the compression ratio of the DVD audio disk.

6. A DVD audio disk reproducing device comprising:

a data receiver (114) to receive audio data reproduced from a disk;

a controller (111) to analyze the audio data reproduced from the disk to thereby generate an audio control signal containing an audio coding mode, a sampling

frequency, a number of channels and quantization information;

an audio decoder (115) having a plurality of decoders, one of the plurality of decoders to decode the audio data received after being selected according to the audio coding mode of the audio data, including multi-channel mixing, sampling frequency converting and requantizing the decoded audio data, according to the audio control signal; and

an audio output (116, 117) to convert the audio data into an analog audio signal.

7. A DVD audio disk reproducing device as claimed in claim 6, wherein the audio decoder (115) comprises:

a stream selector (212) to select one of a plurality of audio streams, which form the audio data according to the audio coding mode;

a linear PCM decoder (213) to decode the selected audio stream if the selected audio stream is a linear PCM audio stream output from the stream selector (212), the linear PCM decoder sampling frequency converting, multi-channel down mixing and requantizing the decoded audio data decoded according to the audio control signal; and

a data decoder (212) to decode the selected audio stream if the selected audio stream is a compressed audio stream output from the stream selector, using a corresponding decompression algorithm and to sampling frequency convert, multi-channel down mix and requantize the decoded audio data, according to the audio control signal.

8. A device for reproducing a DVD video/audio disk, comprising:

a data receiver (314) to receive data retrieved from the disk;

a controller (311) to analyze the data retrieved from the disk to discriminate a kind of the disk, the controller (311) generating an audio control signal containing a video control signal, an audio coding mode, a sampling frequency, a number of channels and quantization information in case of the DVD video disk, or generating only the audio control signal in case of the DVD audio disk;

a stream parser (412) to separate the analyzed data output from the data receiver into video and audio data;

a video decoder (415) to decode the video data output from the stream parser (412);

a video output (415, 416, 318) to NTSC encode the decoded video data, and convert the encoded video data to an analog video signal;

an audio decoder (413) having a plurality of decoders, one of the decoders being selected according to the audio coding mode of the audio data to thereby decode the received audio data, including multi-channel mixing, sampling frequency converting and requantizing the audio data decoded, according to the audio control signal; and

an audio output (414) to convert the decoded audio data to an analog audio signal.

9. A DVD video/audio disk reproducing device as claimed in claim 8, wherein the audio decoder (413) comprises:

a stream selector audio streams which form the audio data according to the audio coding mode;

a linear PCM decoder to decode the selected audio stream is the selected audio stream is a linear PCM audio stream output from the stream selector, the linear PCM decoder sampling frequency converting, multi-channel down mixing and requantizing the decoded audio data according to the audio control signal; and

a data decoder to decode the selected audio stream if the selected audio stream is a compressed audio stream output from the stream selector, using a corresponding decompression algorithm, the data decoder sampling frequency converting, multi-channel down mixing and requantizing the audio data decoded, according to the audio control signal.

10. A method for reproducing a DVD audio disk having information areas each having a title information management table recorded therein, and respective data areas each having sequential audio packs recorded therein, the method comprising the steps of:

reading the title information management table for a title to be reproduced, and confirming an audio coding mode, sampling frequency, quantization bit number and channel number of the audio data recorded relating to the title;

setting the audio decoding mode according to the confirmation;

controlling the DVD audio disk in a playback mode, decoding the audio data according to the set audio decoding mode and performing sampling frequency conversion, multi-channel down mixing and requantization of the decoded data according to the audio coding mode to generate processed decoded audio data; and

converting the processed decoded audio data to an analog signal.

11. A method for reproducing a DVD audio disk having information areas each having a title information management table recorded therein, and respective data areas each having sequential audio packs recorded therein, the method comprising the steps of:

reading the title information management table of a title to be reproduced, and discriminating a kind of the DVD disk recorded;

confirming video control information and audio control information containing a coding mode, sampling frequency, quantization bit number and channel number of the audio data in case of the DVD disk in the discrimination step, or confirming only the audio control information in case of the DVD audio disk;

## EP 0 855 715 A2

setting an audio decoding mode according to the confirmation in case of the DVD audio disk;

controlling the DVD audio disk in a playback mode, decoding the audio data according to an audio coding mode and performing sampling frequency conversion, multi-channel down mixing and requantization of the decoded data according to the audio coding mode, to generate processed decoded data; and

converting the processed decoded audio data to an analog signal.
